React.js cheatsheet

React is a JavaScript library for building user interfaces. This guide targets React v15 to v16.

Components

```
import React from 'react'
import ReactDOM from 'react-dom'
```

```
class Hello extends React.Component {
  render () {
    return <div className='message-box'>
      Hello {this.props.name}
    </div>
  }
}
```

```
const el = document.body
ReactDOM.render(<Hello name='John' />, el)
```

Use the React.js jsfiddle to start hacking. (or the unofficial jsbin)

Children

```
<AlertBox>

</AlertBox>
```

```
class AlertBox extends Component {
  render () {
    return <div className='alert-box'>

    </div>
  }
}
```

Import multiple exports

```
import React, {Component} from 'react'
import ReactDOM from 'react-dom'
```

```
class Hello extends Component {
  ...
}
```

States

```
constructor(props) {
  super(props)
  this.state = { username: undefined }
}
```

```
this.setState({ username: 'rstacruz' })
```

```
render () {

  ...
}
```

Use states (`this.state`) to manage dynamic data.

With Babel you can use proposal-class-fields and get rid of constructor

```
class Hello extends Component {
  state = { username: undefined };
  ...
}
```

Properties

```
<Video fullscreen={true} autoplay={false} />
```

```
render () {

  ...
}
```

Use `this.props` to access properties passed to the component.

See: Properties

Nesting

```
class Info extends Component {
  render () {
    const { avatar, username } = this.props

    return <div>
      <UserAvatar src={avatar} />
      <UserProfile username={username} />
    </div>
  }
}
```

As of React v16.2.0, fragments can be used to return multiple children without adding extra wrapping nodes to the DOM.

Children are passed as the `children` property.

See: States

```
import React, {
  Component,
  Fragment
} from 'react'

class Info extends Component {
  render () {
    const { avatar, username } = this.props

    return (
      <Fragment>
        <UserAvatar src={avatar} />
        <UserProfile username={username} />
      </Fragment>
    )
  }
}
```

Nest components to separate concerns.

See: Composing Components

Defaults

Setting default props

```
  color: 'blue'
}
```

See: defaultProps

Setting default state

```
class Hello extends Component {
  constructor (props) {
    super(props)

  }
}
```

Set the default state in the `constructor()`.

And without constructor using Babel with proposal-class-fields.

```
class Hello extends Component {

}
```

See: Setting the default state

Other components

Functional components

```
  return <div className='message-box'>
    Hello {name}
  </div>
}
```

Functional components have no state. Also, their `props` are passed as the first parameter to a function.

See: Function and Class Components

Pure components

```
import React, {PureComponent} from 'react'

  ...
}
```

Performance-optimized version of `React.Component`. Doesn't rerender if props/state hasn't changed.

See: Pure components

Component API

```
this.forceUpdate()
```

```
this.setState({ ... })
this.setState(state => { ... })
```

```
this.state
this.props
```

These methods and properties are available for `Component` instances.

See: Component API

Lifecycle

Mounting

`constructor` (props)	Before rendering #
`componentWillMount()`	Don't use this #
`render()`	Render #
`componentDidMount()`	After rendering (DOM available) #
`componentWillUnmount()`	Before DOM removal #
`componentDidCatch()`	Catch errors (16+) #

Set initial the state on `constructor()`. Add DOM event handlers, timers (etc) on `componentDidMount()`, then remove them on `componentWillUnmount()`.

Updating

`componentDidUpdate` (prevProps, prevState, snapshot)	Use `setState()` here, but remember to compare props
`shouldComponentUpdate` (newProps, newState)	Skips `render()` if returns false
`render()`	Render
`componentDidUpdate` (prevProps, prevState)	Operate on the DOM here

Called when parents change properties and `.setState()`. These are not called for initial renders.

See: Component specs

Hooks (New)

State Hook

```
import React, { useState } from 'react';

function Example() {
  // Declare a new state variable, which we'll call "count"

  return (
    <div>
      <p>You clicked {count} times</p>

        Click me
      </button>
    </div>
  );
}
```

Hooks are a new addition in React 16.8.

See: Hooks at a Glance

Building your own hooks

Define FriendStatus

```
import React, { useState, useEffect } from 'react';

function FriendStatus(props) {
  const [isOnline, setIsOnline] = useState(null);

  useEffect(() => {
    function handleStatusChange(status) {
      setIsOnline(status.isOnline);
    }

  }, [props.friend.id]);

  if (isOnline === null) {
    return 'Loading...';
  }
  return isOnline ? 'Online' : 'Offline';
}
```

Declaring multiple state variables

```
function ExampleWithManyStates() {
  // Declare multiple state variables!
  const [age, setAge] = useState(42);
  const [fruit, setFruit] = useState('banana');
  const [todos, setTodos] = useState([{ text: 'Learn Hooks' }]);
  // ...
}
```

Effect hook

```
import React, { useState, useEffect } from 'react';

function Example() {
  const [count, setCount] = useState(0);
```

```
  return (
    <div>
      <p>You clicked {count} times</p>
      <button onClick={() => setCount(count + 1)}>
        Click me
      </button>
    </div>
  );
}
```

If you're familiar with React class lifecycle methods, you can think of `useEffect` Hook as `componentDidMount`, `componentDidUpdate`, and `componentWillUnmount` combined.

By default, React runs the effects after every render — including the first render.

Hooks API Reference

Also see: Hooks FAQ

Basic Hooks

`useState`(initialState)

Effects may also optionally specify how to “clean up” after them by returning a function.

Use FriendStatus

```
function FriendStatus(props) {

  if (isOnline === null) {
    return 'Loading...';
  }
  return isOnline ? 'Online' : 'Offline';
}
```

See: Building Your Own Hooks

`useEffect`(() => { ... })	
`useContext`(MyContext)	value returned from `React.createContext`

Full details: Basic Hooks

Additional Hooks

`useReducer`(reducer, initialArg, init)	
`useCallback`(() => { ... })	
`useMemo`(() => { ... })	
`useRef`(initialValue)	
`useImperativeHandle`(ref, () => { ... })	
`useLayoutEffect`	identical to `useEffect`, but it fires synchronously after all DOM mutations
`useDebugValue`(value)	display a label for custom hooks in React DevTools

Full details: Additional Hooks

DOM nodes

References

```
class MyComponent extends Component {
  render () {
    return <div>

    </div>
  }

  componentDidMount () {

  }
}
```

Allows access to DOM nodes.

DOM Events

```
class MyComponent extends Component {
  render () {
    <input type="text"
        value={this.state.value}

  }

  onChange (event) {

  }
}
```

Pass functions to attributes like onChange.

See: Refs and the DOM

See: Events

Other features

Transferring props

```
<VideoPlayer src="video.mp4" />
```

```
class VideoPlayer extends Component {
  render () {

  }
}
```

Propagates `src="..."` down to the sub-component.

See Transferring props

Top-level API

```
React.createClass({ ... })
React.isValidElement(c)
```

```
ReactDOM.render(<Component />, domnode, [callback])
ReactDOM.unmountComponentAtNode(domnode)
```

```
ReactDOMServer.renderToString(<Component />)
ReactDOMServer.renderToStaticMarkup(<Component />)
```

There are more, but these are most common.

See: React top-level API

JSX patterns

Style shorthand

```
const style = { height: 10 }
return <div style={style}></div>
```

```
return <div style={{ margin: 0, padding: 0 }}></div>
```

See: Inline styles

Inner HTML

```
function markdownify() { return "<p>...</p>"; }
<div dangerouslySetInnerHTML={{__html: markdownify()}} />
```

See: Dangerously set innerHTML

Conditionals

```
<Fragment>
  {showMyComponent
    ? <MyComponent />
```

Lists

```
class TodoList extends Component {
  render () {
    const { items } = this.props

    return <ul>
```

```
    : <OtherComponent />}
</Fragment>
```

Short-circuit evaluation

```
<Fragment>
  {showPopup && <Popup />}
  ...
</Fragment>
```

New features

Returning multiple elements

You can return multiple elements as arrays or fragments.

Arrays

```
render () {
  // Don't forget the keys!

}
```

Fragments

```
render () {
  // Fragments don't require keys!

}
```

See: Fragments and strings

Returning strings

```
render() {

}
```

You can return just a string.

See: Fragments and strings

Portals

```
render () {

}
```

This renders `this.props.children` into any location in the DOM.

See: Portals

```
    </ul>
  }
}
```

Always supply a key property.

Errors

```
class MyComponent extends Component {
  ...
}
```

Catch errors via `componentDidCatch`. (React 16+)

See: Error handling in React 16

Hydration

```
const el = document.getElementById('app')
```

Use `ReactDOM.hydrate` instead of using `ReactDOM.render` if you're rendering over the output of ReactDOMServer.

See: Hydrate

Property validation

PropTypes

```
import PropTypes from 'prop-types'
```

See: Typechecking with PropTypes

any	Anything
Basic	
string	
number	
func	Function
bool	True or false
Enum	
oneOf(any)	Enum types
oneOfType(type array)	Union
Array	
array	
arrayOf(...)	
Object	
object	
objectOf(...)	Object with values of a certain type
instanceOf(...)	Instance of a class
shape(...)	
Elements	
element	React element
node	DOM node
Required	
(···).isRequired	Required

Basic types

```
MyComponent.propTypes = {
  email:      PropTypes.string,
  seats:      PropTypes.number,
  callback:   PropTypes.func,
  isClosed:   PropTypes.bool,
  any:        PropTypes.any
}
```

Enumerables (oneOf)

```
MyCo.propTypes = {
  direction: PropTypes.oneOf([
    'left', 'right'
  ])
}
```

Custom validation

```
MyCo.propTypes = {
  customProp: (props, key, componentName) => {
    if (!/matchme/.test(props[key])) {
      return new Error('Validation failed!')
    }
  }
}
```

Required types

```
MyCo.propTypes = {
  name:  PropTypes.string.isRequired
}
```

Elements

```
MyCo.propTypes = {
  // React element
  element: PropTypes.element,

  // num, string, element, or an array of those
  node: PropTypes.node
}
```

Arrays and objects

```
MyCo.propTypes = {
  list: PropTypes.array,
  ages: PropTypes.arrayOf(PropTypes.number),
  user: PropTypes.object,
  user: PropTypes.objectOf(PropTypes.number),
  message: PropTypes.instanceOf(Message)
}
```

```
MyCo.propTypes = {
  user: PropTypes.shape({
    name: PropTypes.string,
    age:  PropTypes.number
  })
}
```

Use `.array[Of]`, `.object[Of]`, `.instanceOf`, `.shape`.
