Spring Boot is gaining popularity like never before, and I know it will be a persistent player in the coming months. There are some features that every technology has and it is very useful in enterprise applications. In this post, we will talk about one feature in particular: profiles.

What Are Profiles?

Every enterprise application has many environments, like:

Dev | Test | Stage | Prod | UAT / Pre-Prod

Each environment requires a setting that is specific to them. For example, in DEV, we do not need to constantly check database consistency. Whereas in TEST and STAGE, we need to. These environments host specific configurations called Profiles.

X

└

T]

We make properties files for each environment and set the profile in the application

accordingly, so it will pick the respective properties (users/login.html) set it up.

REFCARDZ (/refcardz) **TREND REPORTS** (/trendreports) **WEBINARS** (/webinars) **ZONES** ▾

This article will demonstrate how to setup Profiles for your Spring Boot application.

Let's start with setting up a Spring Boot application from the Spring Starter (<https://start.spring.io/>).

SPRING INITIALIZR bootstrap your application now

Generate a Maven Project ▾ with Java ▾ and Spring Boot 2.0.4 ▾

Project Metadata

Generate Project ⌵ ⌵

Don't know what to look for? Want more options? [Switch to the full version.](#)

Next, we need to import the project into STS as a Maven Project. Below is the project structure:

X

In this demo application, we will see how to configure different databases at runtime based on the specific environment by their respective profiles.

REFCARDZ (/refcardz) · **TREND REPORTS** (/trendreports) · **WEBINARS** (/webinars) · **ZONES** ▾

As the DB connection is better to be kept in a property file, it remains external to an application and can be changed. We will do so here. But, Spring Boot — by default — provides just one property file (`application.properties`). So, how will we segregate the properties based on the environment?

The solution would be to create more property files and add the "profile" name as the suffix and configure Spring Boot to pick the appropriate properties based on the profile.

Then, we need to create three `application.properties` :

1. `application-dev.properties`
2. `application-test.properties`
3. `application-prod.properties`

Of course, the `application.properties` will remain as a master properties file, but *if we override any key in the profile-specific file, the latter will gain precedence.*

I will now define DB configuration properties for in respective properties file and add code in `DBConfiguration.class` to pick the appropriate settings.

Here is the base `application.properties` :

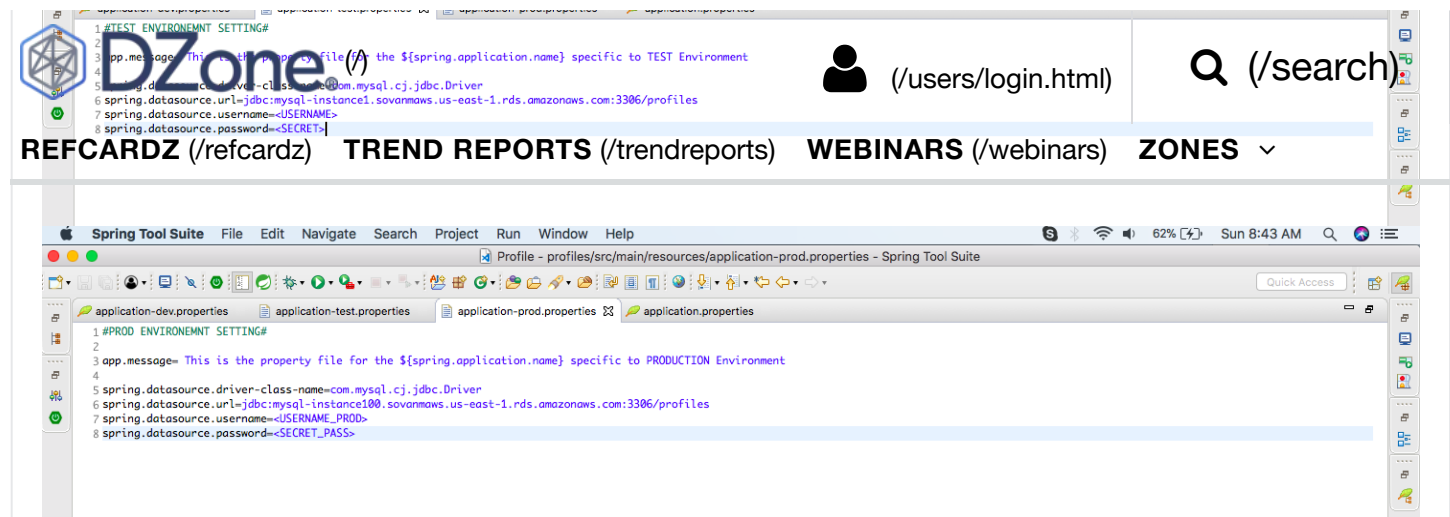

In DEV, we will use an in-memory database:

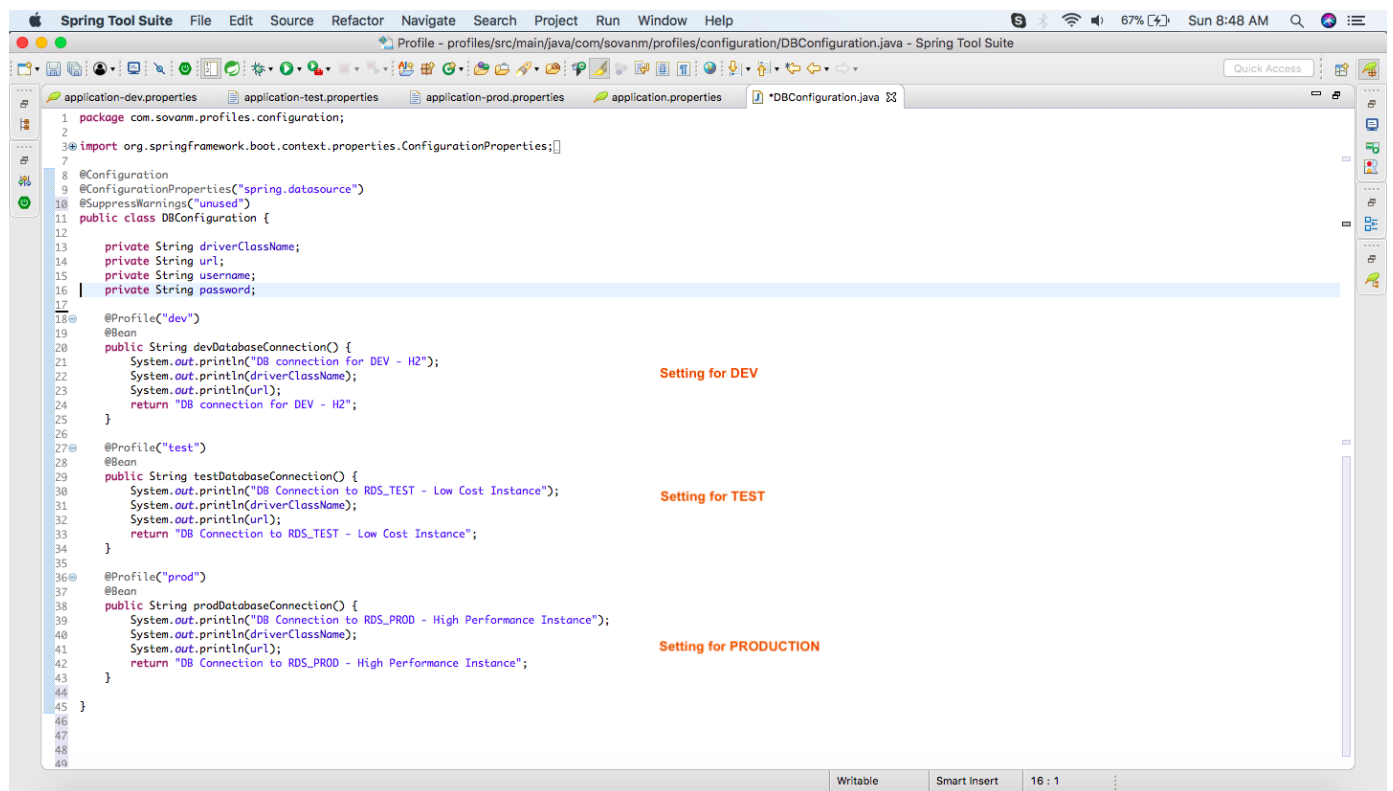

In
w

X

Now, we are done with properties files. Let's configure in the `DBConfiguration.class` to pick the correct one.

We have used the `@Profile("Dev")` to let the system know that this is the BEAN that should be picked up when we set the application profile to DEV. The other two beans will not be created at all.

One last setting is how to let the system know that this is DEV, TEST, or PROD. But, how do we do this?

We will use the `application.properties` to use the key below:

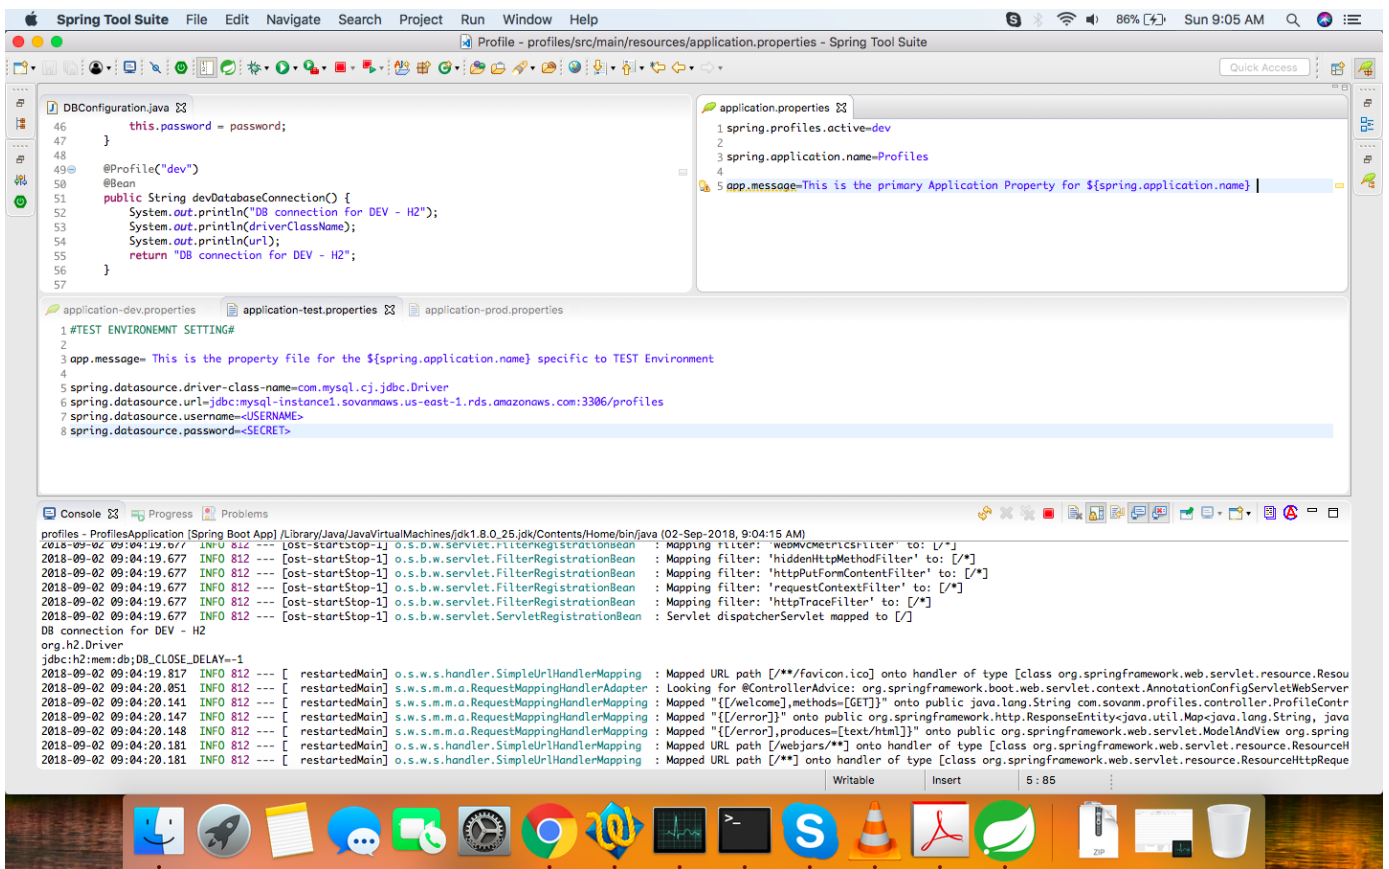

X

From here Spring Boot will know which profile to pick. Let's run the application now! (users/login.html) (search)

With the profile in DEV mode, it should pick H2 DB

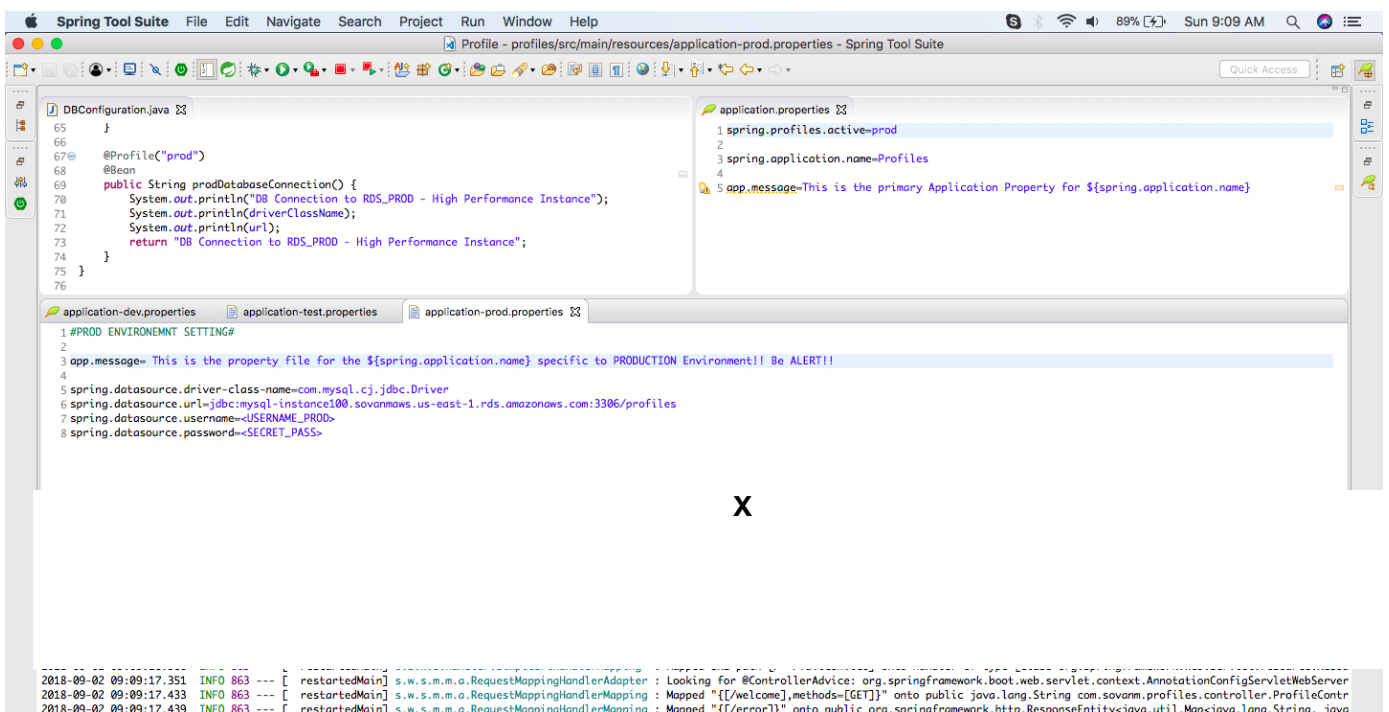

RECORDZ (/recordz) TREND REPORTS (/trendreports) WEBINARS (/webinars) ZONES

localhost:8080/welcome

This is the property file for the Profiles specific to DEV Environment

Now, change the profile to PROD. We will see MySQL with High Config for DB. This should be picked, and the message will be overridden with the PROD message.

That's it! We just have to change it once at the `application.properties` to let Spring Boot know which environment the code is deployed in, and it will do the magic with the setting.
