Arrays in Java, conceptually, are no different than in other programming languages.

- Arrays are contiguous memory locations storing only one type of item in a sequence.
- Arrays provide index-based access i.e. the first element of the array is stored at the **0th** index, 2nd element is stored on **1st** index and so on.
- Note that, in Java, arrays are also objects that inherit the **Object** class, and implement the [Serializable](#) as well as [Cloneable](#) interfaces.
- We can store all kinds of primitive values or objects in an array.
- Java supports single dimensional or multi-dimensional arrays, both.

The [java.util.Arrays](#) class provides many useful *static* methods to work with arrays and perform common operations on them.
